Definition

Glomerulonephritis (glomerular nephritis, GN) denotes group of primary and secondary acute and chronic kidney diseases (usually affecting both kidneys) mostly characterised by immune mediated inflammation in the glomerular capillaries and the glomerular basement membrane (GBM), that may present with isolated hematuria and/or proteinuria, or as a nephrotic syndrome, a nephritic syndrome, a hypertensive syndrome and their combinations associated with progressive kidney failure, high cholesterol and anemia.

http://bestpractice.bmj.com/best-practice/monograph/207/basics.html
USMLE TEST

Multiple patients present to your office with hematuria following an outbreak of Group A Streptococcus. Biopsy reveals that all of the patients have the same disease, characterized by large, hypercellular glomeruli with neutrophil infiltration. Which patient has the best prognosis?

1. 65-year-old nulliparous woman
2. 50-year-old man with a history of strep infection
3. 8-year-old boy who undergoes no treatment
4. 38-year-old man with sickle cell trait
5. 18-year-old man treated with corticosteroids
USMLE TEST

The correct answer is 3

Age is the most important prognostic factor in post-streptococcal glomerulonephritis. Ninety-five percent of affected children recover completely, compared with 25% of adults over 60 years old.

Incorrect answers:
1, 2, & 4: Older adults are more likely to progress to end-stage renal disease.
5: Corticosteroids may be used in refractory cases but are unlikely to result in a cure.
Epidemiology 1

• For every patient with clinically apparent GN, approximately 5 to 10 patients have undiagnosed subclinical disease.
• Incidence rates of primary GN vary between 0.2/100,000/year and 2.5/100,000/year.
• Focal segmental glomerulosclerosis is the most common cause of GN, especially among black patients.
• Membranous nephropathy (MN) used to be the most common biopsy diagnosis in adult patients.
Epidemiology 2

• Idiopathic MN is more common in white men >40 years of age.

• MN is associated with lupus in young women and with hepatitis B in children.

• The incidence of IgA nephropathy is at least 2.5/100,000/year in adults; this disease can exist subclinically.
Incidence is given as cases per year; prevalence is given as cases per 100,000 population. \(^a\) Data from children. \(^b\) Data from adults. \(^c\) Data provided by Dr Tray Hunley, Division of Pediatric Nephrology, Vanderbilt Children's Hospital, Nashville, TN, USA.
Epidemiology
(Chronic GN and chronic kidney disease)

Etiology of chronic kidney disease (CKD): HTN = Hypertension, CGN = Chronic Glomerulonephritis, DM = Diabetes Mellitus, PKD = Polycystic Kidney Disease, CPN = Chronic Pyelonephritis, OU = Obstructive Nephropathy

http://www.annalsafrmed.org/article.asp?issn=1596-3519;year=2012;volume=11;issue=1;spage=21;epage=26;aulast=Chijioke
Risk Factors 1

- Disorders of the lymphatic system.
- Blood disorders.
- Family or personal history of cancer or malignant tumors.
- Exposure to chemicals such as toxic hydrocarbon solvents.
- Recurring strep infections or skin abscesses.
- Viral infections.

http://www.home-remedies-for-you.com/gglomerulonephritis/causes.html
Risk Factors 2

• Heart infections.

• Specific diseases (amyloidosis, vasculitis, polyarthritis, Goodpasture syndrome, IgA nephropathy, NSAIDs, lupus nephritis, Henoch-Schönlein purpura, etc.).

http://www.home-remedies-for-you.com/glomerulonephritis/causes.html
Etiology 1

• Renal-limited glomerulopathy or glomerulopathy-complicating systemic disease.
• Inflammation due to leukocyte infiltration, antibody deposition, and complement activation.
• Other causes:
  • Infections (e.g., group A beta-hemolytic *Streptococcus*, other bacterial infections, viruses).
  • Systemic inflammatory (e.g., SLE, rheumatoid arthritis).
Etiology 2

- Drugs (e.g., penicillamine, NSAIDs, captopril, heroin).
- Metabolic disorders (diabetes mellitus, thyroiditis).
- Malignancy (e.g., lung and colorectal cancer, Hodgkin lymphoma)
- Hereditary (Fabry disease, Alport syndrome, etc.).
- Deposition diseases (amyloidosis, light chain deposition disease).
Etiology
(Causes of Renal Disease and GN)

Prerenal causes
These include any condition that reduces blood flow to the kidneys.
- Hypovolemia
- Diarrhoea, vomiting
- Bleeding, Burns, CCF
- Ascitis, Anasarca
- Renal A/V thrombosis

Intrinsic causes
These may be glomerulovascular or tubulointerstitial.
- Autoimmune disorders: Vasculitis, anti GBM dis
- Diabetes, tubular dis
- Toxins, infections, metabolic

Postrenal causes
These result in obstruction of urine flow from the kidneys.
- Ureteral, urethral obstruction. Stone, papillary necrosis, bladder dis, prostate, drugs, cancer.
A 9-year-old Caucasian girl presents to your office with hematuria. An electron micrograph of her renal biopsy is shown below in Figure A. Which of the following is the most likely composition of the structures marked by the white arrows?

1. Albumin
2. Non-enzymatic glycosylation
3. IgA
4. IgG
5. IgG, IgM, C3
The correct answer is 5

The patient's presentation and EM are consistent with post-streptococcal (postinfectious) glomerulonephritis. The white arrows demonstrate epimembranous immune complex deposits of IgG, IgM and C3. Figure A shows the classic epimembranous immune complex deposition on EM.

Incorrect answers:
1: Albumin is not the structure seen in this EM.
2: Non-enzymatic glycosylation would not be visible on EM.
3: While IgA nephropathy has granular EM deposits, they are located in the mesangium and not in the sub-epithelium.
4: The deposits identified contain IgM and C3 in addition to IgG.
Mechanisms
(Key Position of Immunologic Response) 1

• Most cases of GN are due to an immunologic response to a variety of different etiologic agents.
• The immunologic response, in turn, activates a number of biological processes (e.g., complement activation, leukocyte recruitment, and release of growth factors and cytokines) that result in glomerular injury and inflammation.
Mechanisms
(Key Position of Immunologic Response) 2

- GN may be isolated to the kidney (primary glomerulonephritis) or be a component of a systemic disorder (secondary glomerulonephritis).
- Humoral (also referred to T helper cell 2-regulated) immune response to a variety of inciting agents results in immunoglobulin deposition and complement activation within the glomeruli.
Mechanisms (Acute GN) 1

- Glomerular lesions are the result of glomerular deposition or in situ formation of immune complexes.
- On gross appearance, the kidneys may be enlarged up to 50%.
- Histopathologic changes include swelling of the glomerular tufts and infiltration with polymorphonucleocytes.
Mechanisms (Acute GN) 2

- Immunofluorescence reveals deposition of immunoglobulins and complement.
- Except in poststreptococcal glomerulonephritis (PSGN), the exact triggers for the formation of the immune complexes are unclear.
- In PSGN, involvement of derivatives of streptococcal proteins has been reported.
Mechanisms
(Chronic GN: Reduction in Nephron Mass) 1

- Reduction in nephron mass from the initial injury reduces the glomerular filtration rate (GFR), that leads to hypertrophy and hyperfiltration of the remaining nephrons and to the initiation of intraglomerular hypertension with further glomerulosclerosis and nephron loss.

- In early renal disease, a substantial decline in the GFR may lead to only slight increases in serum creatinine levels.
Mechanisms
(Chronic GN: Reduction in Nephron Mass) 2

- Azotemia (i.e., a rise in blood urea nitrogen (BUN) and serum creatinine levels) is apparent when the GFR decreases to less than 60-70 mL/min.
Mechanisms
(Chronic GN: Reduction in in the Glomerular Filtration Rate) 1

• Decreased production of erythropoietin, thus resulting in anemia.
• Decreased production of vitamin D, resulting in hypocalcemia, secondary hyperparathyroidism, hyperphosphatemia, and renal osteodystrophy.
• Reduction in acid, potassium, salt, and water excretion, resulting in acidosis, hyperkalemia, hypertension, and edema.
Mechanisms
(Chronic GN: Reduction in the Glomerular Filtration Rate) 2

- Platelet dysfunction, leading to increased bleeding tendencies.
- Accumulation of toxic waste products (uremic toxins) affects virtually all organ systems.
- Uremia occurs at a GFR of approximately 10 mL/min.
Mechanisms
(Possible Pathogenic Mechanism of Poststreptococcal GN)

Abbreviations: GADPH - streptococcal glyceraldehyde phosphate dehydrogenase, GBM - glomerular basement membrane, MMP - matrix metalloproteinase, SpeB - streptococcal cationic proteinase exotoxin B.
Mechanisms
(Focal Necrotizing GN)

The formation of crescents and the glomerular capillary necrosis (hematoxylin and eosin stain; original magnification 400).

http://www.nature.com/nrneph/journal/v5/n5/fig_tab/nrneph.2009.51_F1.html
Mechanisms
(Focal Necrotizing GN)

The time-dependent changes in the pro-inflammatory and anti-inflammatory functions of leukocyte subsets during the course of crescentic GN.

http://www.nature.com/nri/journal/v13/n10/full/nri3523.html
Mechanisms
(Chronic Renal Failure can Result from a GN)

All forms of renal failure are characterized by a reduction in the GFR, reflecting a corresponding reduction in the number of functional nephrons.
A 21-year-old male presents to your office with hematuria 3 days after the onset of a productive cough and fever. Following renal biopsy, immunofluorescence shows granular IgA deposits in the glomerular mesangium. Which of the following do you suspect in this patient?

The correct answer is 2

Hematuria and immunofluorescence findings of IgA deposits in the mesangium suggest Berger’s disease (IgA glomerulonephropathy). Berger’s disease can occur concurrently or within several days of an infection.

Incorrect answers:
1: Lipoid nephrosis, or minimal change syndrome, is the most common cause of nephrotic syndrome in young children. IgA is not present in glomeruli,
3: Post-streptococcal glomerulonephritis classically occurs in children weeks, not days, after an infection with group A hemolytic streptococci. Immunofluorescence shows C3 and IgG, but not IgA,
4: Systemic lupus erythematosus commonly causes a diffuse proliferative glomerulonephritis. IgA is not present in glomeruli,
5: HIV infection is associated with focal segmental glomerulosclerosis, a cause of nephrotic syndrome in adults with refractory hypertension. IgA is not present in glomeruli.
Classification
(International Classification of Diseases (ICD))

XIV Diseases of the genitourinary system.

N00-N08 Glomerular diseases.

  N00 Acute nephritic syndrome.
  N01 Rapidly progressive nephritic syndrome.
  N02 Recurrent and persistent hematuria.
  N03 Chronic nephritic syndrome.
  N04 Nephrotic syndrome.
Classiﬁcation
(International Classiﬁcation of Diseases (ICD))

XIV Diseases of the genitourinary system.

N00-N08 Glomerular diseases.
  N05 Unspeciﬁed nephritic syndrome.
  N06 Isolated proteinuria with speciﬁed morphological lesion.
  N07 Hereditary nephropathy, not elsewhere classified.
  N08 Glomerular disorders in diseases classiﬁed elsewhere.

http://apps.who.int/classifications/icd10/browse/2016/en#/N00.2
Classification
(Primary and Secondary GN)

• Primary: the pathologic process is limited to the kidney and not part of a systemic disease manifestation

• Secondary: systemic lupus erythematosus (SLE), Henoch-Schonlein purpura, Wegener granulomatosis, microscopic polyangiitis, cryoglobulinemia, thrombotic microangiopathies, deposition diseases (amyloidosis, light chain deposition disease), malignancies (Hodgkin lymphoma, lung and colorectal cancer).
Classification (Nephrotic/Nephritic) 1

Nephrotic syndrome (nephrotic-range proteinuria, hypoalbuminemia, hyperlipidemia, and edema):

• deposition diseases,
• minimal change disease,

• focal and segmental glomerulosclerosis,
• membranous nephropathy,
• membranoproliferative GN.

https://online.epocrates.com/diseases/20721/Glomerulonephritis/Definition
Classification
(Nephrotic/Nephritic) 2

Nephritic syndrome (hematuria, subnephrotic-range proteinuria, and hypertension (HTN)):
- IgA nephropathy,
- postinfectious GN,
- rapidly progressive GN,
- vasculitis,
- anti–glomerular basement membrane (anti-GBM) GN.
Classification
(Nephritic and rapidly progressive GN (RPGN))

- Granular immune deposits (immune complex mediated GN).
- Linear immune deposits (anti-GBM GN).
- Pauci-immune GN.
Classification
(Severity)

- Mild: asymptomatic isolated hematuria or proteinuria <2 g.
- Moderate to severe: symptomatic proteinuria, hematuria, and reduced GFR (nephrotic and nephritic syndromes, and rapidly progressive GN).
Clinical Investigation
(Symptoms)

Symptoms depend on whether patient have the acute or chronic form, and the cause and may include:

• pink or cola-colored urine from red blood cells in urine (hematuria),
• foamy urine due to excess protein (proteinuria),
• high blood pressure (HTN),
• fluid retention (edema) with swelling evident in face, hands, feet and abdomen,
• fatigue from anemia or kidney failure.

http://www.mayoclinic.org/diseases-conditions/glomerulonephritis/basics/symptoms/con-20024691
Clinical Investigation
(Post-Streptococcal Glomerulonephritis)
Clinical Investigation
(Edema In Acute Renal Failure)
Clinical Investigation
(Sings) 1

• Asymptomatic proteinuria (150 mg - 3 g per day).
• Microscopic hematuria: >2 red blood cells (RBCs) per high power field in spun urine.
• Macroscopic hematuria: brown or smoky urine.
• Nephrotic syndrome: proteinuria >3.5 g/day, hypoalbuminemia less than 3.5 g/dL, edema, hypercholesterolemia and lipiduria.
Clinical Investigation
(Sings) 2

- Nephritic syndrome: abrupt onset with oliguria, hematuria, proteinuria, azotemia, edema and hypertension.
- Rapidly progressive glomerulonephritis (RPGN): proteinuria, hematuria and renal failure developing over days to a week.
- Chronic GN: proteinuria, hypertension, renal failure and smooth contracted kidneys on ultrasonography (USG) examination.
Clinical Investigation
(Modalities)

• About half of the people with acute GN have no symptoms. If symptoms do occur, the first to appear are tissue swelling, low volume dark urine.

• In RPGN weakness, fatigue, and fever are the most frequent early symptoms. These patients have edema and usually produce very little urine.

• Because chronic GN usually causes only very mild or subtle symptoms, it goes undetected for a long time in most patients. The disease may progress to kidney failure.

Clinical Investigation
(Complications)

• Acute kidney failure.
• Chronic kidney disease (CKD).
• High blood pressure.
• Nephrotic syndrome.
A 25-year-old male visits his primary care physician with complaints of hemoptysis and dysuria. Serum blood urea nitrogen and creatinine are elevated, blood pressure is 160/100 mm Hg, and urinalysis shows hematuria and RBC casts. A 24-hour urine excretion yields 1 gm/day protein. A kidney biopsy is obtained, and immunofluorescence shows linear IgG staining in the glomeruli. Which of the following antibodies is likely pathogenic for this patient’s disease?

The correct answer is 4

The patient’s clinical picture, laboratory data, urinalysis, and light microscopy are consistent with Goodpasture syndrome. Goodpasture syndrome is a type II hypersensitivity reaction characterized by autoantibodies to the glomerular basement membrane (anti-GBM).

Incorrect answers:
1: Anti-DNA antibody is associated with the diffuse proliferative GN of SLE.
2: Anti-neutrophil cytoplasmic antibody (C-ANCA) is associated with Wegener granulomatosis.
3: Anti-neutrophil perinuclear antibody (P-ANCA) is associated with microscopic polyarteritis.
5: Anti-phospholipid antibody is associated with an autoimmune, hypercoagulable state.

Diagnosis

• Clinical data,
• Urine examination.
• Blood tests: complete blood cell count (CBC), inflammatory markers and special tests (anti-streptolysin O (ASLO), anti-neutrophil cytoplasmic antibodies (ANCA), Anti-GBM antibody complement levels, antinuclear antibodies,
• Imaging.
• Biopsy of the kidney.

https://en.wikipedia.org/wiki/Glomerulonephritis#Signs_and_symptoms
Diagnosis
(Clinical Data) 1

• Clinical features vary depending on the etiology and may include one or a combination of the following: hematuria (macroscopic or more commonly microscopic), proteinuria, and edema (characteristic of nephrotic syndrome).

• Hypertension may or may not be present, it is uncommon.

https://online.epocrates.com/diseases/20731/Glomerulonephritis/Diagnostic-Approach
Diagnosis
(Clinical Data) 2

• Patients may have features of the underlying disorder, for example:
  • joint pain, rash, and hemoptysis in vasculitis,
  • fever and sore throat in streptococcal infections,
  • jaundice in hepatitis B and C,
  • weight loss in malignancies,
  • stigmata of IV drug use.

https://online.epocrates.com/diseases/20731/Glomerulonephritis/Diagnostic-Approach
Diagnosis
(Laboratory tests: 1)

• A urinalysis and urine microscopy is generally the first test, and further testing is prompted on the basis of the results.

• Other initial recommended tests include GFR and creatinine evaluation, 24-hour urine collection, CBC, metabolic profile, and lipid profile.

• Urinalysis and renal function tests show hematuria and proteinuria. In complicated disease GFR and creatinine may suggest reduced renal function.
Diagnosis
(Laboratory tests: 2)

• Proteinuria, measured by 24-hour urine collection, is generally <3.5 g/day, but if it is >3.5 g/day, patients are classified as having nephrotic-range proteinuria and may have full nephrotic syndrome (hyperlipidemia, hypoalbuminemia, edema, nephrotic-range proteinuria).

• Hematuria is characterized by dysmorphic RBCs and formation of RBC casts that are best seen in freshly prepared urine sediments.
Diagnosis
(Laboratory tests: 3)

• Anemia, hyperglycemia (if diabetic), hyperlipidemia (nephrotic picture), and hypoalbuminemia (nephrotic picture) may also be evident from the CBC, and from metabolic and lipid profiles.

• If urinalysis indicates GN, subsequent tests are ordered to determine the etiology and hence to guide the treatment.

https://online.epocrates.com/diseases/20731/Glomerulonephritis/Diagnostic-Approach
Diagnosis
(Laboratory tests: 4)

• Specific serologic testing for systemic causes include erythrocyte sedimentation rate (ESR), complement, ANCA, anti-GBM antibodies, monoclonal protein on serum or urine electrophoresis, antistreptococcal antibodies, circulating cryoglobulin, HIV serology, hepatitis B virus serology, hepatitis C virus serology, and drug toxicology screen.

https://online.epocrates.com/diseases/20731/Glomerulonephritis/Diagnostic-Approach
Diagnosis
(Ultrasound)

Morphological aspect of the kidney with acute kidney injury at B-mode renal ultrasound.

Diagnosis
(Biopsy of the Kidney)

Rapidly progressive ("crescentic") GN. Formation of crescents is initiated by passage of fibrin into the Bowman space. Fibrin stimulates the proliferation of parietal cells of Bowman capsule, and an influx of monocytes. Rapid growing and fibrosis of crescents compresses the capillary loops and decreases the Bowman space which leads to renal failure. (H&E, ob. x20). http://www.pathologyatlas.ro/rapidly-progressive-crescentic-glomerulonephritis.php
# Diagnosis
(Distinguishing Acute Kidney Injury From Chronic Kidney Disease)

https://online.epocrates.com/diseases/20731/Glomerulonephritis/Diagnostic-Approach
Diagnosis
(Staging CKD)

1. Normal GFR (≥ 90 mL/min/1.73 m²) plus either persistent albuminuria or known structural or hereditary renal disease.

2. GFR 60 to 89 mL/min/1.73 m².

3. GFR 30 to 59 mL/min/1.73 m².

4. GFR 15 to 29 mL/min/1.73 m².

5. GFR < 15 mL/min/1.73 m².

GFR (in mL/min/1.73 m²) in CKD can be estimated by: 186.3 \times (\text{serum creatinine})^{-1.154} \times (\text{age})^{-0.203}. The result is multiplied by 0.742 if the patient is female and by 1.21 if the patient is African American. For female African Americans, the result is multiplied by 0.742 \times 1.21 (0.898).

</table>
A 37-year-old man presents with significant hematuria and hemoptysis. The results of the immunofluorescence are shown in Figure A. What pathologic changes would be expected under light microscopy?

1. "Wire looping" of the capillaries
2. Hypercellular glomeruli
3. Crescentic glomerulonephritis
4. Focal proliferative glomerulonephritis
5. Normal glomeruli

USMLE TEST

The correct answer is 3

The clinical scenario and attached image are consistent with Goodpasture syndrome, a type of rapidly progressive crescentic glomerulonephritis (RPGN).

Incorrect answers:
1: "Wire looping" of the capillaries on light microscopy (LM) is typical of diffuse proliferative glomerulonephritis and is associated with SLE.
2: Hypercellular glomeruli on LM are typical of post-streptococcal glomerulonephritis.
4: Focal proliferative changes on LM are characteristic of IgA nephropathy or Berger disease, which can be associated with Henoch-Schoenlein Purpura if extra-renal symptoms are present.
5: Normal glomeruli on LM could be seen in minimal change disease which is a nephrotic, not nephritic disorder.
Treatment
(Lifestyle and Dietary Advice)

• People with chronic GN be encouraged to undertake physical activity compatible with cardiovascular health and tolerance (aiming for at least 30 min five times per week), achieve a healthy weight (body mass index 20–25 kg/m², according to country-specific demographics), and stop smoking.

• People with chronic GN receive expert dietary advice and information in the context of an education program, tailored to severity of CKD and the need to intervene on salt, phosphate, potassium, and protein intake where indicated.

Treatment

(Goal of Specific Therapy)

• The goal of specific therapy for GN is to reverse the renal damage or to preserve the renal function, that is monitored by checking renal function and the degree of proteinuria.

• Most of the specific treatment include plasmapheresis, corticosteroid therapy, and immunosuppression.

• Complications such as HTN and hyperlipidemia should be managed appropriately to counteract cardiovascular events, as well as to delay progression of renal pathology.

https://online.epocrates.com/diseases/20741/Glomerulonephritis/Treatment-Approach
Treatment
(Mild Disease)

Patients who present with isolated hematuria, minimal or no proteinuria, and a normal GFR have a better outcome and may not need specific therapies other than treating the systemic cause (e.g., antibiotics, antivirals, withdrawal of the causative drug).
Treatment
(Moderate to Severe Disease) 1

• Patients with hematuria, proteinuria, and reduced GFR are managed with specific therapies targeted at reversing the underlying etiology, for example, antibiotics in acute nephritic poststreptococcal GN.

• Nonspecific pharmacologic measures that reduce proteinuria and are also first-line considerations for controlling HTN, including angiotensin-converting enzyme (ACE) or angiotensin-II receptor antagonists.
Treatment
(Moderate to Severe Disease) 2

• Edema is controlled by salt-restricted diet (1–2 g/day), oral or intravenous (IV) loop diuretics alone or combined with thiazide.

• Severe disease presenting as nephrotic syndrome is usually treated with corticosteroids and immunosuppressants.
Treatment
(Anticoagulation and Statins)

• Anticoagulation with low molecular weight heparin or warfarin is mandatory if serum albumin is below 2 g/dL with one or more of the following: proteinuria greater than 10 g/day, body mass index greater than 35 kg/m², family history of thromboembolism, congestive heart failure, recent abdominal or orthopedic surgery or prolonged immobilization.

• Statins are well tolerated and effective in correcting lipid profile, but not proven to reduce cardiovascular events.
Treatment
(Rapidly Progressive Disease (RPGN))

• Categorized into the following:
  • Antiglomerular basement membrane (linear type),
  • Immune-complex mediated (granular type): postinfectious causes, connective tissue disease, IgA nephropathy, and membranoproliferative GN,
  • Pauci-immune: Wegener granulomatosis and polyarteritis nodosa.
• Corticosteroids and immunosuppressant therapy with or without plasmapheresis are the mainstay of treatment for severe and progressive disease.

Treatment
(End-stage Renal Disease Therapy)

• Hemodialysis.
• Peritoneal dialysis.
• Renal transplantation.
A 62-year-old man presents to his primary care doctor complaining of recent-onset hemoptysis. He has not had any fevers, night sweats, or weight loss. He recently traveled to Italy with his wife. He has a 5 pack-year smoking history. On review of systems, he reports that his urine has been “red-tinged” for several months. Urinalysis reveals the findings shown in Figure A. He is referred to a nephrologist and undergoes a renal biopsy. Immunofluorescence staining of the biopsy is shown in Figure B. Which of the following is the most likely underlying pathogenesis of his disease?

The correct answer is 2

This patient has pulmonary hemorrhage and nephritic syndrome. His renal biopsy shows linear deposition of antibodies along the basement membrane in the glomerulus, a finding characteristic of Goodpasture disease.

Incorrect answers:
1: Goodpasture disease is a type II hypersensitivity reaction, 3: C-ANCA disorders include granulomatosis with polyangiitis (Wegner's), which can cause pulmonary and renal symptoms. However, this diagnosis would not show a linear fluorescent staining pattern, 4: Tuberculosis is a mycobacterial infection that can affect many organ systems. However, this man does not have significant risk factors for tuberculosis, and his biopsy is diagnostic of Goodpasture disease, 5: He has not had weight loss or other systemic signs suggestive of metastatic malignancy. Moreover, his biopsy results are diagnostic of an autoimmune process.
Treatment

(Lifestyle and Dietary Advice)

• People with chronic GN be encouraged to undertake physical activity compatible with cardiovascular health and tolerance (aiming for at least 30 min five times per week), achieve a healthy weight (body mass index 20–25 kg/m², according to country-specific demographics), and stop smoking.

• People with chronic GN receive expert dietary advice and information in the context of an education program, tailored to severity of CKD and the need to intervene on salt, phosphate, potassium, and protein intake where indicated.
Prognosis 1

• Most epidemic cases follow a course ending in complete patient recovery (as many as 100%). The mortality of acute GN has been reported at 0-7%.

• Sporadic cases of acute GN often progress to a chronic GN. This progression occurs in as many as 30% of adult patients and 10% of pediatric patients. GN is the most common cause of CKD (25%).

• Approximately 15% of patients at 3 years and 2% of patients at 7-10 years may have persistent mild proteinuria.
Prognosis 2

• Generally, the prognosis is worse in patients with heavy proteinuria, severe hypertension, and significant elevations of creatinine level.

• Serum creatinine levels and the proportion of crescents were the most important predictors of developing CKD.

http://emedicine.medscape.com/article/239278-overview#showall
Prophylaxis

• There may be no way to prevent most forms of GN.
• Some interventions may be beneficial:
  • prompt treatment of a strep infection,
  • prompt treatment of a viral infection,
  • control high blood pressure
  • control blood sugar.
